

How to measure a series laser diode

Overview

The light-current-voltage (LIV) sweep test is a fundamental measurement to determine the operating characteristics of a laser diode (LD). In the LIV test, current applied to the laser diode is swept and the intensity of the resulting emitted light is measured using a photo detector. Digital multimeters can test diodes using one of two methods: Diode Test mode: almost always the best approach. Note: In some cases it may be necessary to remove one end of the diode from the circuit in. Understanding how to properly test a laser diode is crucial for troubleshooting malfunctions, ensuring optimal performance, and preventing potential damage. It explains why testing is essential at various stages, from development and manufacturing quality control to the burn-in process for eliminating. Characterizing an active electronic component such as a diode requires the test engineer to perform an I-V curve measurement.
