

Network security device probes

Overview

Probes use SNMP and other types of Internet protocol, such as TCP, HTTP, or command-line, to retrieve data by polling a device. Once data has been received, the probe feeds data into a display within your network monitoring software solution. Probes poll devices . A network probe is an essential tool for network administrators, IT security professionals, and network engineers to ensure real-time network monitoring and optimize network performance. A Probe is a Windows application that resides on a computer, such as a server, within a customer network behind the. Authenticated network scans provide an agentless way to discover and assess network infrastructure devices, such as switches, routers, WLAN controllers, firewalls, and VPN gateways. For more information, see Authenticated network scans. NETSCOUT's network detection and response solution enables teams to investigate activity before, during, and after an event with a focus on network visibility and investigation. Different techniques for accomplishing this are used depending on the traffic and application.
